Abstract
Background: Hepatitis B virus (HBV) is a double-stranded circular DNA virus and member of the Hepadnaviridae family of viruses.
Methods: This cross sectional study was done on 250 nursing staff. There were total 263 nursing staff in this hospital out of which 250 enrolled voluntarily to participate in this study. The objective, nature and benefits of this study were explained and informed & written consent was taken from all participants. All nursing staff was interviewed structured self-completed quaternaries.
Results: Hepatitis B virus (HBV) infection is an occupational health hazard preventable by vaccination. 78% of nursing staff know that Hep B is a vaccine preventable. 42% of participants knew that getting vaccinated offers a protection from infection for 15 years. 16% of nursing staff are aware that a titre value of more than 10 ml U/ml is needed for protection from Hepatitis B infection. 84% of nursing staff are willing to motivate others and encourage them to get vaccinated against Hepatitis B.
Conclusion: This study highlighted the need to have nursing staff educated regarding significance of immunization against vaccine preventable disease.
Keywords: Hepatitis, Immunization, Liver

Introduction:
Hepatitis B virus (HBV) is a double-stranded circular DNA virus and member of the Hepadnaviridae family of viruses.¹
Hepatitis B is an important cause of inflammation of the liver that is potentially life threatening as well as preventable. According to World Health Organization, 7.8 million people die each year from hepatitis B infection globally and another 240 million people are chronically infected (defined as positive HBsAg for minimum 6 months).² Nonetheless it's an important occupational hazard for health care professionals. However, through vaccination and safety measures, it can be prevented successfully. Bangladesh is in intermediate zone of prevalence of hepatitis B infection and the
lifetime risk of acquisition of hepatitis B in these areas is 20 to 60%\(^3\). In one study the prevalence of hepatitis B in Bangladeshi general population was 5.4% with a male predominance \(^3\). Vertical transmission, transmission through unsafe sex, unsafe injections and body fluid like blood remains the most common route of infection for hepatitis B virus \(^4\). Health-care workers have the highest occupational risk for hepatitis B infection.

**Materials and Methods**

This cross sectional study was done on 250 nursing staff. There were total 263 nursing staff in this hospital out of which 250 enrolled voluntarily to participate in this study. The objective, nature and benefits of this study were explained and informed written consent was taken from all participants. All nursing staff were interviewed structured self-completed quaternaries.

**Results**

A total of 250 nursing staff responded to the questionnaire, 76% were female, and 24% were male.

Hepatitis B virus (HBV) infection is an occupational health hazard preventable by vaccination. 78% of nursing staff know that Hep B is vaccine preventable.

42% of participants knew that getting vaccinated offers a protection from infection for 15 years. 16% of nursing staff are aware that a titre value of more than 10 ml U/ml is needed for protection from Hepatitis B infection. 84% of nursing staff are willing to motivate others and encourage them to get vaccinated against Hepatitis B.

**Discussion**

Hepatitis B virus (HBV) infection is an occupational risk for health care professionals especially in developing countries which have a carrier rate of about 4%. Every year HBV infection accounts for 1.1 million cases. As such, incidence of HBV infection can only be brought down by giving proper education regarding its transmission and also getting nursing students immunized with Hepatitis B vaccine. The number of students getting immunized showed an increase due to awareness created to them during their medical curriculum.

The present study concludes that there is an increased awareness among nursing students regarding the need to be vaccinated against Hepatitis B. However all the students were not vaccinated against Hepatitis B, which make them vulnerable to the disease. The reason as to why vaccination was not taken by few students needs to be addressed and make them realise the importance of vaccination. Since nursing students are at increased risk of acquiring needle stick injury, and also due to increased prevalence rate of Hepatitis B in India, nursing students should mandatorily be vaccinated upon entry into the nursing college. It is recommended that a policy be in place for complete vaccination and health education of all nursing students upon enrolling into nursing course. It’s also important to routinely check antibody titre and if its below 10 ml U/ml a booster dose be advised.
Conclusion
This study highlighted the need to have nursing staff educated regarding significance of immunization against vaccine preventable disease.
